# About Me...

- My name is **Morteza Mostajab**
- B.Sc. Computer Engineering at  
*Hamedan University of Technology, Iran*
- M.Sc. Computer Science at  
*Technische Universität München*
- Working as Researcher at  
*Fraunhofer IGD, Darmstadt*
- Research interests:  
*Real-time physically-based rendering*  
*(Rasterization-based or Ray-tracing)*  
*Virtual reality*  
*Computer graphics and visualization*  
*Game Programming*

# Inspiration

- Games, Animations, Movies with Special Effects,...

(a) Last Ninja 3

(b) Gears of War

(c) Ratatouille

(d) The lord of the rings

- My firsts...

(e) First Computer (Commodore 64)

(f) First IBM  
compatiable PC (Atari 2600)  
(80286)

# Outline

- 1 Introduction

Figure 1: Final results of this master thesis.

# Motivation

- **Goal:** Use virtual reality to help engineers getting a better **understanding** of simulations, make **investigation** in flow field features easier.
- Virtual reality applications demands 75-140 frames per second scene update and rendering to reduce **latency**.
- **Initial motivation:**
  - **Immersive Streamline Demo:** a demo which user could stand in a simulation model to understand flow field features by:
    - Prototype demo which placed the user virtually in simulation model.
    - User could interact with virtual world by moving streamlines' seeding plane.
    - User could walk around in the simulation model, look closer into streamlines to understand flow field's features better.

# Immersive Streamline Demo

**Figure 2: Immersive Streamlines** was a prototype demo done at Fraunhofer IGD. The user is able to move inside the virtual world, interact with it, and look closely at the flow visualization results. The image shows a stereo pair, which is displayed on Oculus Rift HMD.

# Problem Definition

- Streamline's computation was 10 frames per second (latency was very visible to user).
- Streamline's accuracy was not high enough (straight lines in streamlines are visible in the screenshot).
- Stream surfaces can provide more information about flow fields features.
- So, we defined **Parallel Stream Surface Computation and Rendering** master thesis to solve these problems.

# Main Contributions

- **Contribution 1:** Using heterogeneous computing:
  - Scale streamline computation on all capable devices.
  - Scale rendering on all graphic processing units.
- **Contribution 2:** Investigation techniques from ray tracing field for application in accurate streamline computation:
  - Using acceleration structures
  - Using ray-packing

# Benefits

- Accurate streamline computation method (using **Runge-Kutta** integration method).
- **Adaptive Runge-Kutta** integration method to adapt steps to maximum integration error.
- Heterogeneous stream surface computation.
- Multi GPU stream surface computation and result

# Related Works

- Parallel stream surface computation for large data sets (Camp et al., 2012).  
proposed a distributed stream surface computation system.
  - **My method is not distributed but uses all available computation devices.**
- Interactive Streak Surface Visualization on the GPU (Buerger et al., 2009).  
Bue+09 samples the simulation mesh on a regular grid, then compute the streak surface.
  - **Reduces accuracy, ignores a lot of information exist in simulation mesh by sampling it on a regular grid.**

# Related Works

- Interactive particle tracing for the exploration of flow fields in virtual environments (Schirski, 2008).  
Sch08 uses the neighboring graph instead of acceleration structure on GPU.
  - **step size needed to be small enough.**
- Fast, Memory-Efficient Cell Location in Unstructured Grids for Visualization (Garth and Joy, 2010).  
introduces cell-tree acceleration structure use it for particle tracing.
  - **I have evaluated more acceleration structures to classify them based on memory requirements and performance.**

# Stream Surface Computation Algorithm (Camp et al., 2012)

**Data:**  $seeds$  list which contains all initial seeding points.

**Result:** Stream Surface Points

**while**  $seeds$  list is not empty **do**

**Tracing:** Trace streamlines originating from seeding points stored in  $seeds$  list and make  $seeds$  empty.

**Refinement:** **for** each pair of adjacent streamlines  $s_1$  and  $s_2$  **do**

$d \leftarrow Distance(s_1, s_2)$

**if**  $d \leq D_{disc}$  **then**

| **Discontinuity:** The surface is discontinued in that area.

**else**

$s_{new} \leftarrow (s_1[0] + s_2[0])/2$

| add  $s_{new}$  to list  $seeds$ .

**end**

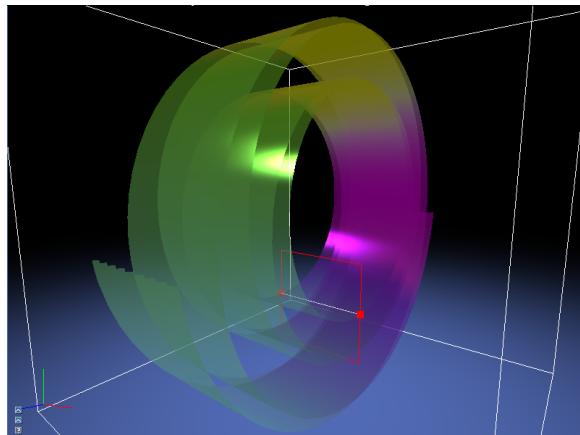

**end**

**end**

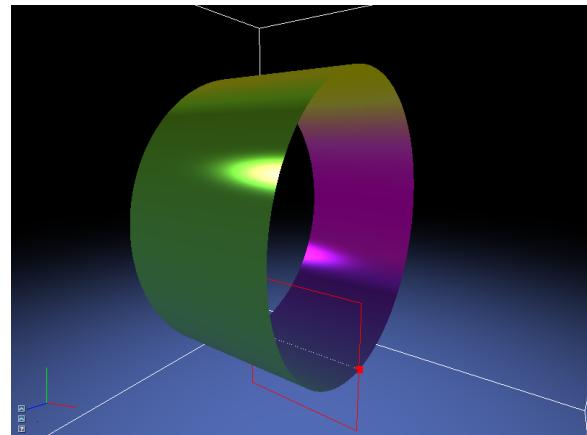

**Algorithm 1:** Stream Surface Computation Algorithm (Camp et al.,

# Accurate Streamline Computation

- Point-Inside-Cell checks & interpolating results inside cells.
- Using *adaptive Runge-Kutta* integration method (Cash-Karp).
- Adaptive stepping (faster and more accurate integration).
- Avoiding early terminations.

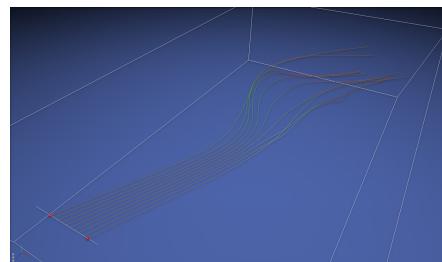

(a) Euler

(b) Cash-Karp

# Heterogeneous Computing Results

- Measured parameters:
  - **Computations per second:** It shows how many times the stream surface can be computed in every second. The unit is number of computation times per second.
  - **Number of seeding points:** Total number of seeding points for producing the final stream surface.

# Wind Tunnel Dataset

Real-time stream surface computation – April 2016  
Seyedmorteza Mostajabodaveh

# Car Dataset

Real-time stream surface computation – April 2016  
Seyedmorteza Mostajabodaveh

# Heterogeneous Computing Results Conclusions

- As expected, the streamline computation is being scaled on all available computation devices.
- Using both GPUS and CPU, the computation performance is doubled.
- Limiting factors:
  - OpenGL operations cannot be parallelized.
  - Synchronization of threads are a overhead.
  - **Dynamic task scheduling** could be a better approach.
- There is an overhead for initializing computations on multiple devices.

# Acceleration Structures

- Grid
- Kd-tree
- Bounding Volume Hierarchy (BVH)
- Cell-tree (Garth and Joy, 2010)

# Why Acceleration Structures?

- Accelerating cell look up for faster streamline computation.
- Ray tracing uses acceleration structures to find **nearest intersection point** in contrast to streamline computation which uses it to **sample result in a specific point**.
- Differences:
  - In streamline computation instead of *Surface Area* Heuristics, *textit{Volume}* Heuristics should be used.
  - *Traversal algorithms* for space partitioning cases does not need *stack*.
  - Hierarchy traversal algorithms need a greedy method to prefer one child to other one during traversal.

# Contrib. 2: Using Acceleration Structures for Streamline Computation Evaluations

- Measured parameters:
  - **Avg. checks per traverse:** Average number of bounding box or point-inside-cell tests done to find the cell surrounding the sample point.
  - **Size in memory:** Size of the constructed acceleration structured in memory.

# Wind Tunnel ( $\sim 2.5$ M Tets, $\sim 133$ MB)

Seyedmorteza Mostajabodaveh

# Wind Tunnel (~12.5 M Tets, ~800 MB)

Real-time stream surface computation – April 2016  
Seyedmorteza Mostajabodaveh

# Wind Tunnel (~54.1 M Tets, ~4.1 GB)

Real-time stream surface computation – April 2016  
Seyedmorteza Mostajabodaveh

# Acceleration Structures Evaluation Conclusion

- When memory is the bottleneck *Cell tree* is suitable (Cell tree size in memory is around 4-6 percent of original dataset).
- Highest performance is achieved using *Grid* (Grid performance is higher than BVH and cell tree when its size is higher than 25 percent of original dataset).
- BVH seems like a balance between memory and performance (BVH size in memory in its highest performance is around 9-11 percent of original dataset).

# Ray Tracing Revisited for Rendering CSG Models Consisting of Higher Order Primitives

**Figure 5:** A complex CAD scene built out of 8,000 individual plant models. In total, the scene consists of more than 100,000,000 non-planar second-order (cylinders, cones, etc.) and forth-order (tori) primitives, ray traced at more than 10 frames per second on 16 CPU cores, including pixel-accurate shadows.

# Benefits

- **On-the-fly compositing.**
  - Boolean set operations are performed on a per-ray basis immediately during rendering.
  - No Preprocessing.
- **Low storage requirement.**
  - small set of parameters for each primitive.
  - No prior triangulation of primitives. – Holding scenes in memory would be possible without triangulation.
- **Pixel-accurate higher order surfaces.**
  - Ray-primitive intersection can be tested directly. – Usually a quadratic equation which is easy to solve (tori has a quartic equation).
  - No discretization artifacts are visible.
  - Surfaces appear perfectly smooth.

# Main Contributions

- a method to apply CSG operations in real-time during ray tracing while keeping the memory overhead low.
- Evaluation of the proposed method in comparison to other well-known rasterization-based real-time CSG model rendering techniques((Goldfeather et al., 1986), and (Stewart et al., 2002)).

# Contribution: Optimized Hitpoint Calculation

```
ray: current ray hitting a primitive
if entering primitive then
| delta := +1;
else
| delta := -1;
end
if positive primitive hit then
| ray.posDepth += delta;
else
| ray.negDepth += delta;
end
if (ray.posDepth > 0) && (ray.negDepth <= 0) then
| ReportHit(); // final hit in layer found
else
| ContinueRay(ray); // still inside a negative medium
end
```

# Analysis of Voxel-Based Ray Tracing

- **Goal:** Instrumenting voxel-based path-tracer with SIMD simulator to measure ray-sorting algorithms impact on SIMD units' efficiency.
- **Main Contribution:** Measure the impact of improving coherency methods (ray sorting) on instruction coherency of the rays.

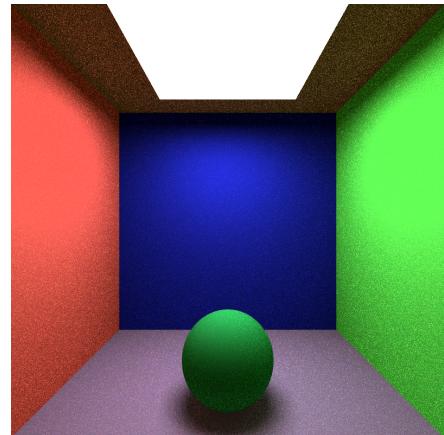

# Basis for Evaluations: Implementing a Voxel-Based Path-Tracer

(e) Soft Shadow with Area Light

(f) Global Illumination with Path Tracing

(g) Cornell Box

All scenes are described with a hierarchy of 3d voxels.

# BVH Traversal Main Operations Classification (1/2)

- **Push and Traverse** Ray is intersecting with both child nodes. One should be chosen and the other one should be kept in the stack.
- **Traverse** Ray is intersecting with one of the child nodes. The traversal path is clear.
- **Leaf Node Intersection** Intersection test should be done for leaf nodes.
- **Finished** Traversal is done.

# BVH Traversal Main Operations Classification (2/2)

```
while Finished ≠ true do
    if CurrNode is InteriorNode then
        if intersection with both childs then
            NextNode ← leftchild
            s.Push(RightChild)                                Push and Traverse
        else
            if intersection with one child then
                | NextNode ← IntersectedChild
            else
                | if not s.empty() then
                    | | NextNode ← s.Pop()
                else
                    | | Finished ← true
                end
            end
        end
    end
else
    Intersect with voxels related to the leafnode to find the
    intersection.                                         Leaf Node Intersection
    if found or s.empty() then
        | Finished ← true
    else
        | NextNode ← s.Pop()
    end
end
end
```

# Our SIMD Simulator

Reset all ray's *InstCounter* elements to zero.

$CurrStage \leftarrow 0$

**while**  $Finished \neq \text{true}$  **do**

**if** All rays has done their first  $CurrStage$  operations **then**

$CurrStage++$

        Continue

**end**

$CurrOp \leftarrow FindNextOperationToExecute(CurrStage)$

    ExecuteSIMDUnitsWithNextOperation( $CurrOp$ )

**if** Any of SIMD Units are done **then**

        | deactivate the SIMD operation unit.

**end**

**end**

# Current Status

- Working at Fraunhofer IGD, Darmstadt as a Researcher.
- Involved in two projects:
  - **VELaSSCo EC Funded Project** (<http://www.velassco.eu/>).
    - Our simulation models are stored in a Hadoop database (HBase) which is running on a HPC.
    - Idea: Doing post processing (mesh simplification, and streamline computation) on the HPC and send the result as triangle mesh for the client.
    - My task is to implement Fraunhofer IGD's visualization client, some of data access queries on HPC side, and streamline computation post processing technique on the HPC side using map-reduce.
  - an industrial project in collaboration with CST AG.
    - Worked on dynamic tessellating arc primitives in real-time on CPU and upload the triangles to the GPU.
  - **Both projects will be already finished and it's a great time to leave Fraunhofer IGD for me**
